Abstract. This study investigated the most important attributes of the 6-year post-graduation income of college graduates who used financial aid during their time at college in the United States. The latest data released by the United States Department of Education was used. Specifically, 1,429 cohorts of graduates from three years (2001, 2003, and 2005) were included in the data analysis. Three attribute selection methods, including filter methods, forward selection, and Genetic Algorithm, were applied to the attribute selection from 30 relevant attributes. We discuss how higher numbers of students in a cohort who grew up in Zip code areas where over 25 percent of the population hold a Professional Degree was predictive of more college graduates being classified as High income.

Keywords: Attribute selection, feature selection, post-graduation income classification, post-graduation income prediction, social stratification.

1 Introduction

Higher education is as an excellent “investment” that should be encouraged by families, schools, communities, and policy makers. The returns of a college degree vis-à-vis a high school diploma has expanded considerably in recent decades. Autor [1] found that this “graduate premium” doubled in real terms between 1979 and 2012. The gap in earnings between the median college educated worker and the median high-school educated worker increased from $17,411 to $34,969 for men, while also increasing from $12,887 to $23,280 for women. Research by Chetty et al. [2] underscores the role of higher education as a key pathway to intergenerational social mobility in the U.S. Further, Hout [3] contends that higher education “makes life better” through a host of social benefits in community relations, health, family stability, and social connections.

Yet as higher education participation has expanded [4], college graduates have become an increasing heterogeneous population with increasingly disparate labor market outcomes [5, 6]. While some graduates are highly successful, others face challenges to gainful employment. Data from the Federal Reserve Bank of New York [7] shows that 43.4 percent of college graduates aged between 22 and 27 graduates
are under-employed or employed in a job that “typically does not require a college
degree”, while 12.7 are employed in “low-wage jobs” that tend to pay below $25,000
per annum. Research has established that field of study [8] and institutional selectivity
[9] are important features in post-graduation incomes. Building on the literature, this
study explored the most important attributes of 6-year post-graduation income of
college graduates who used student aid from the U.S. Department of Education, and
to what extent of accuracy the select attributes can be used to classify post-graduation
income. The research questions were: (1) What are the most important attributes of
post-graduation income of college students who graduate with debt repayment
obligations? and (2) To what extent can the selected attributes classify post-
graduation income of college students who graduate with debt repayment obligations?

2 Research Design

2.1 Data Collection

The data for this study was the latest dataset – released in October 2015 – by College
Scorecard under the U.S. Department of Education [10]. This dataset only covered
students who used financial aid during their college study period. Each row in the data
stands for a student cohort admitted to a certain university. The data ranged from
1996 to 2013, but the 6-year post-graduation income data are only available for the
is the mean value of the 6-year post-graduation income of a student cohort. Attributes
were filtered based on domain knowledge. Factors deemed less relevant were
excluded, such as latitude of the institution and percent of students who passed away
within 6 years after graduation.

30 potential attributes (see Appendix A) under five groups were included in this
study. The groups are: (1) School, (2) Admission, (3) Cost, (4) Student Cohort, and
(5) Socioeconomic Status of Students. Some attributes in certain groups are not
available before 2000, such as admission rate in the Admission Group. Thus, only
three years of data, including 2001, 2003, and 2005 were used. 1,429 cohorts were
included for the data analysis. The response variable, mean income value of each
cohort, was discretized into four classes based on the American Individual Income
Distribution; including Very low (0 to 25,000), Low (25,000 to 37,500), Middle
(37,500 to 50,000), and High (Above 50,000) [11].

2.2 Data Analysis

Two steps of preprocessing were applied to the collected data before the analysis: (1)
Standardization: Standardization, transforming raw scores to z-scores, was applied to
all the numerical attributes. There were 28 numerical attributes in total; (2) One-hot
encoding: One-hot encoding techniques were applied to all the nominal attributes.
There were 2 nominal attributes.

Three attribute selection methods were applied and compared, including filter
methods, stepwise wrapper methods, and naturally inspired algorithms. The filter
methods applied in this study included five algorithms: (1) OneR algorithm, (2) Relief-based selection, (3) Chi-square selection, (4) Gain-ratio-based selection, and (5) Information-gain-based selection.

Both stepwise wrapper methods and naturally inspired algorithms need to have an evaluation function to work. Logistic regression was chosen as the evaluation function of both for stability and efficiency. The stepwise wrapper methods included forward and backward selection. Forward selection starts with no attributes in the model, and tests the addition of each attribute using certain comparison criteria. Backward selection starts with all candidate attributes, and tests deletion of each attribute using certain criteria. Only forward selection was used in this study.

The naturally inspired algorithm implemented was the Genetic Algorithm. Genetic Algorithm is a computational algorithm with origins in the field of biology. The tools that Genetic Algorithm uses have marks of genetic systems, including generation selection, crossover, and mutation [12]. We implemented the simple form of Genetic Algorithm described by Goldberg [13].

Weighted average F1-score was chosen as the primary evaluation criterion, because there exists an imbalance in the four income classes. A classifier that primarily guesses based on the majority class would achieve a small advantage in accuracy, but would perform worse in terms of the F1-score. Also, classification accuracy rate was used as the secondary evaluation criterion. Ten-fold cross validation was used for the estimation of both F1-score and accuracy rate.

3 Results

Five filter methods, including (1) OneR algorithm, (2) Relief-based selection, (3) Chi-square selection, (4) Gain-ratio-based selection, and (5) Information-gain-based selection, were applied to the attribute selection. The 10-fold cross validation scheme was implemented in Weka [14]. As opposed to the cross-validation in prediction or classification, no training or testing is involved in the cross-validation scheme of attribute selection. Under such a scheme, the dataset was randomly sectioned into 10 folds, and only 9 folds were used for subset attribute selection in each round. There were 10 rounds in total. The 10 selection results were summarized afterwards. The attributes selected by at least three out of the five methods (60%) were selected, yielding 14 selected attributes in total. The arithmetic mean of each attribute’s ordinal ranking across all selection methods was also calculated, to enable measuring of attribute usefulness. For each single-attribute evaluator, the output of Weka showed the average merit and average rank of each attribute over the 10 folds (see Table 1).

Same as the implementation of filter methods, 10-fold cross validation scheme in Weka was used for more stable estimates. Attributes selected by at least six out of ten folds (60%) were selected, yielding 9 selected attributes in total. The selected attributes are presented in Table 2.

In alignment with the prior two attribute selection approaches, 10-fold cross validation scheme in Weka was used. Attributes selected by at least six out of ten folds (60%) were selected, yielding 22 selected attributes in total (see Table 3).

The Genetic Algorithm (GA) was as the third option for attribute selection. The settings of the GA were as follows:

- Population size: 500
- Fitness function: Classification accuracy derived from Logistic Regression
- Selection Method: Tournament selection
- Crossover Type: Two-point crossover
- Crossover Rate: 0.6
- Mutation Rate: 0.03
- Stopping Criteria: 60 generations

*Votes Column: The percentage of folds that selected the corresponding attributes.

Logistic Regression and Support Vector Machine with Pearson VII function kernel were used to compare the performance of the three selected attribute subsets. Ten-fold cross validation was used to estimate the classification accuracy for each classification method (see Table 4 and Table 5 for individual classification results). As the most selective feature selection method (9 attributes selected), Forward Selection achieved acceptable F-measure. Although less selective (22 attributes selected), Genetic Algorithm outperformed the other two methods by both F-measure and accuracy.

4 Conclusion

Using College Scorecard data [10], we selected the most important factors predicting the 6-year post-graduation income of college students who used financial aid during their time at college. We compared three attribute selection methods: filter methods, forward selection, and Genetic Algorithm, in terms of classification accuracy on students’ post-graduation income. We found that the attribute subset selected by the Genetic Algorithm outperformed the other two subsets when using logistic regression and support vector machine as the classification algorithm.

We wish to draw attention to how higher numbers of students in a cohort who grew up in Zip code areas where over 25 percent of the population hold a Professional Degree was predictive of more college graduates likely being classified as High income. This finding is aligned with evidence about how geography or “where you grow up” impacts life outcomes. Chetty et al. [15] identified that areas with lower racial segregation and income inequality, but higher social capital and family stability are associated with greater opportunities for intergenerational social mobility. In the current research, the role of geography for post-graduation incomes in the case of neighborhood Professional Degree attainment signifies social stratification in graduate labor markets. The finding may stem from unequal access to support for education and careers. This would reinforce the Effectively Maintained Inequality model that predicts that as access to education widens, higher socio-economic status students will seek “horizontal differentiation” by accessing qualitatively distinctive or superior types of education that maintain their advantage in society [17,18].

We are not arguing that young people from disadvantaged neighborhoods should not attend higher education. Attaining a bachelor’s degree remains an excellent “investment” to enhance career prospects. Yet our findings showing a disparity of post-graduation income according to “where you grow up” suggests a need for greater support for students both in college access and in transitions to the labor market, especially given rising tuition fees and associated concerns about student debt [19].

---

1 Social capital represents trust, solidarity, and reciprocity in collective social interactions and engagement in community-based activities [16].

30 potential attributes include:

Group One: School information
1. School Type (e.g. private school)
2. Predominant Awarded Degrees (e.g., bachelor degree)
3. Student Size
4. Instructional Expenditure per Student
5. Ratio between Part-time and Full-time Students
6. Degree Completion Rate
7. Average Faculty Salary

Group Two: Admission information
8. Admission Rate
9. Average SAT Score

Group Three: Cost information
10. In-State Tuition
11. Out-of-State Tuition

Group Four: Student information
12. Percentage of White Students
13. Percentage of Black Students
14. Percentage of Asian Students
15. Percentage of American Indian Students
16. Percentage of Hispanic Students
17. Percentage of Female Students
18. Percentage of First-Generation Students
19. Average Age of Entering College
20. Average Debt

Group Five: Family and community information
21. Percentage of Students whose Family Income was classified as Low
22. Percentage of Students whose Family Income was classified as Lower Middle
23. Percentage of Students whose Family Income was classified as Higher Middle
24. Percentage of Students whose Family Income was classified as High
25. Percentage of Students whose Family Income was classified as Very High
26. Percentage of Students whose Parents were 1st Generation College Student
27. Percentage of Students whose Parents Have a Middle School Degree
28. Percentage of Students whose Parents Have a High School Degree
29. Percentage of Students whose Parents Have a Post-High-School Degree
30. Population from Students' Zip Codes over 25% with a Professional Degree
